1. Executive Summary

Healthcare is global, and clinical conversations routinely cross language boundaries. A cardiologist in Dubai may conduct a consultation in Arabic, switch to English for medical terminology, and document in either language. A family physician in Montreal navigates French and English within a single patient encounter. ClinixSummary is designed for this multilingual reality.

2. The Multilingual Challenge

Multilingual clinical documentation presents challenges that monolingual systems cannot address:

- Code-switching — clinicians and patients routinely switch between languages mid-sentence, particularly for medical terminology.
- Medical terminology asymmetry — some clinical concepts have standard terms in one language but not another.
- Documentation language preference — the language spoken in the consultation may differ from the required documentation language.
- Regulatory requirements — different jurisdictions mandate documentation in specific languages.

3. Supported Languages

ClinixSummary currently supports six languages with full clinical documentation capability:

- English — All medical specialties with comprehensive terminology coverage.
- French — Full support including Québécois French medical terminology.
- Spanish — Latin American and European Spanish variants.
- Portuguese — Brazilian and European Portuguese.
- Italian — Full specialty coverage.
- Arabic — With complete right-to-left interface and documentation support.

4. Code-Switching: The Real-World Challenge

4.1 How Code-Switching Works in Practice

In a typical multilingual consultation, a clinician might say: “Alors, vous avez des douleurs thoraciques depuis deux semaines? And the pain is worse when you lie down?” This single exchange contains French medical history-taking and English follow-up — both of which must be correctly captured and documented.

4.2 ClinixSummary’s Approach

ClinixSummary’s multilingual models are trained on real clinical speech that includes code-switching. The system:

- Detects language switches at the sub-sentence level without requiring explicit language selection.

- Maintains clinical context across language boundaries — a symptom described in Arabic is correctly linked to an assessment stated in English.
- Generates the final note in the clinician's preferred documentation language, regardless of which languages were spoken.
- Preserves patient-reported quotes in their original language when clinically relevant.

5. Real-World Deployment Cases

5.1 Dubai — Arabic/English

A multi-specialty clinic in Dubai uses ClinixSummary for consultations conducted primarily in Arabic with English medical terminology. Notes are generated in English for insurance compatibility, with Arabic summaries for patient records. The code-switching model handles the frequent Arabic-English transitions without requiring clinician intervention.

5.2 Montreal — French/English

A family practice in Montreal serves a bilingual patient population. Consultations may be conducted entirely in French, entirely in English, or in a mix. ClinixSummary generates notes in the clinician's preferred language while correctly processing input in either language.

6. Conclusion

Multilingual clinical documentation is not a niche requirement — it is the reality of modern healthcare. ClinixSummary's native multilingual capability, including real-time code-switching, enables clinicians worldwide to document naturally in the languages they and their patients actually speak.
